

1, Explain behaviour of hub device

* It is a layer 1 device and we can use to connect multiple network devices. It is a broadcast domain device, and large collision domain device, due to this device traffic flow collision will increase, we can use to connect only small number of network devices to communicate.

2, Explain behaviour of switch device

* Switch is a layer 2 device, switch is one of the most intelligent network device. It is used to connect multiple network device. It will act as broadcast and unicast device.

* It maintains MAC table, it performs address learning to maintain MAC table, in this MAC table it will automatically update the port and device connected MAC address in MAC table.

* This ARP table will update every 5 mins. based on the model switch having different modes and ports and each port having different speeds.

3, Explain behaviour of router device

* Router is a layer 3 device. and it is used to break the broadcast domain. and it is a unicast device. It contains unicast device, * Router will only connect different network

segment
^ devices.

* Router maintains routing table that having list of route table which is directly connected devices routes.

* mostly Router used to connect LAN networks to WAN network devices.
